Mortality

### ABSTRACT

**Background:** No studies have yet examined the interrelationship of malnutrition and low handgrip strength in terms of mortality. The aim of the present study was to evaluate the potential synergistic effects of malnutrition and low handgrip strength on mortality among older adults living in a retirement community.

**Methods:** This prospective longitudinal cohort study recruited subjects aged 65 years and over from a veterans care home in Taiwan in 2013. Nutritional status was assessed using the Mini-Nutritional Assessment-Short Form (MNA-SF, malnutrition was MNA-SF < 12); muscle strength was measured by handgrip strength (low handgrip strength was handgrip strength < 26 kg). The Kaplan-Meier method with the log-rank test was used to estimate survival differences between groups and Cox proportional regression model was used to estimate the adjusted difference in 4-year all-cause mortality between groups.

**Results:** Recruited for the present study were 333 male participants (mean age 85.4 ± 5.7 years). Of these, 50.2% had malnutrition and 54.7% had low handgrip strength. Compared with subjects with no malnutrition and low handgrip strength, those with malnutrition had significantly greater risk of 4-year all-cause mortality (adjusted hazards ratio: 2.05, 95% confident interval [CI]: 1.04–4.01; hazard ratio increased to 3.41 (95% CI 1.93–6.04) for those with both malnutrition and low handgrip strength.

**Conclusions:** Malnutrition was an independent risk factor for 4-year all-cause mortality and low handgrip strength with malnutrition synergistically increased the mortality risk. Further study is needed to confirm the effectiveness of integrated programs to assist those at risk.

### 1. Introduction

Malnutrition is highly prevalent and significantly associated with geriatric syndromes in community-dwelling older adults (Verlaan et al., 2017; Wei, Nyunt, Gao, Wee, & Ng, 2017). The prevalence of malnutrition is generally above 30% in independent community-dwelling older adults and is up to 50% in those with poor physical function (Cereda et al., 2016; Kaiser et al., 2010). Risk of malnutrition in older adults is related to old age, chronic diseases, frailty, loss of interest in life, impaired efficacy in swallowing, polypharmacy, and institutionalization (Chapman, 2006; Favaro-Moreira et al., 2016). The

adverse health outcomes associated with malnutrition include increasing severity of disability (Sharkey, 2002), more function decline (Chu et al., 2017), higher prevalence of comorbidities (e.g., delirium) (Chu et al., 2016), longer hospital stays (Ruiz et al., 2018), higher readmission rates (Chu et al., 2017), significant economic burden (Ruiz et al., 2018), decreased quality of life (Keller, Ostbye, & Goy, 2004), and higher mortality rates (Wei et al., 2018).

Handgrip strength, suggested by the Academy of Nutrition and Dietetics and the American Society for Parenteral and Enteral Nutrition (ASPEN) to screen functional status, is reported to be associated with decline in cognitive function, falls, postsurgical complications,

functional decline, and even death (Alfaro-Acha et al., 2006; Bohannon, 2001; McLean et al., 2014; Rantanen et al., 1999, 2003; Stessman, Rottenberg, Fischer, Hammerman-Rozenberg, & Jacobs, 2017; Xue, Walston, Fried, & Beamer, 2011). In addition to handgrip strength, muscle mass and gait speed are the compartments of sarcopenia. However, handgrip strength is considered as a key characteristic of sarcopenia, by the European Working Group on Sarcopenia in Older People (EWGSOP) (Cruz-Jentoft et al., 2019), and was reported as a more practical measure of nutrition assessment than the 5-meter walk by McNicholl et al., due to its higher complete rate (McNicholl et al., 2018). Most previous studies have focused on independent correlations of malnutrition or low handgrip strength with mortality, but the effect on mortality of the two together remains unclear. An association between malnutrition and low handgrip strength in older adults was recently reported (Kim, Jeon, & Jeong, 2019), implying a possible synergistic effect on all-cause mortality in older adults. Thus, the aim of the present study was to evaluate the potential synergistic effect of malnutrition and low handgrip strength on mortality among older adults living in a retirement community in Taiwan.

## 2. Materials and methods

### 2.1. Participant recruitment

Residents of a Veteran's Care Home (VCH) were invited to participate in this prospective longitudinal cohort study in 2013 [43]. VCH is a veteran's retirement community and is similar to assisted living in the United States. All participants aged 65 years and over were enrolled when they provided signed informed consent. Subjects with the following conditions were excluded: (1) inability to communicate with research nurses, (2) inability or unwillingness to provide informed consent, (3) diagnosed with moderate or advanced dementia, and (4) inability to perform the physical measurement, such as handgrip strength. The study protocol was reviewed and approved by the Institutional Review Board of Kaohsiung Veterans General Hospital (IRB19-1234).

### 2.2. Comprehensive geriatric assessments

Comprehensive geriatric assessments were performed in all participants by well-trained research nurses who collected demographic data, including age, educational level, marital status, smoking status, body mass index (BMI, kg/m<sup>2</sup>), Charlson's Comorbidity Index (CCI) (Charlson, Pompei, Ales, & MacKenzie, 1987), polypharmacy (defined as currently using more than 4 drugs for over 2 weeks), cognitive impairment (defined as scores < 24 on the Chinese version of the Mini-Mental State Examination, MMSE) (Folstein, Folstein, & McHugh, 1975), depressive symptoms (defined by scores ≥ 5 on the 15-item Chinese Geriatric Depression Scale, GDS-15) (Nyunt, Fones, Niti, & Ng, 2009), malnutrition (defined by scores < 12 on the Mini-Nutritional Assessment-Short Form, MNA-SF) (Kaiser et al., 2009), pain severity (assessed by visual analogue scale, VAS score) (Huskisson, 1974), and baseline Activities of Daily Living (ADLs, assessed by Barthel Index, BI) (Collin, Wade, Davies, & Horne, 1988). The mortality dates were recorded until December 2017 from the VCH medical records.

### 2.3. Definition and assessment of handgrip strength and gait speed

Muscle strength was measured by handgrip strength using a digital dynamometer (TTM-YD, Tokyo, Japan). The best measurement of three trials using the dominant hand was recorded. Usual gait speed was measured by using a timed 6-meter walking test (with or without walking aids) with a static start throughout the hallway without deceleration. Low handgrip strength was defined as handgrip strength < 26 kg and low gait speed was defined as < 0.8 m/s according to the definition of the Asian Working Group for Sarcopenia

(Chen et al., 2014).

### 2.4. Statistical analysis

All continuous variables were presented as mean ± standard deviation (SD), and categorical data were presented as numbers (percentage). Student's *t*-test was used to compare continuous variables between groups and the chi-squared test or Fisher exact test was used to compare categorical variables between groups, as appropriate. To evaluate the synergistic effect of malnutrition and low handgrip strength on 4-year all-cause mortality, participants were classified into one of four groups: good nutrition with good handgrip strength (Group 1), good nutrition with low handgrip strength (Group 2), malnutrition with good handgrip strength (Group 3), and malnutrition with low handgrip strength (Group 4). The Kaplan-Meier method with the log-rank test was used to estimate the survival difference between groups and Cox proportional regression model was used to estimate the difference in 4-year all-cause mortality between groups after adjusting for the covariates of age, CCI, polypharmacy, cognitive impairment, BI, slow gait speed, depressive symptoms, and hearing impairment. All statistical analyses were performed using IBM SPSS Statistics for Windows, Version 21.0 IBM Corp., Armonk, NY). P < 0.05 was used to indicate statistical significance.

## 3. Results

### 3.1. Clinical characteristics of participants

In total, 333 male participants were recruited for the present study. The mean age was 85.4 ± 5.7 years. Among them, 167 (50.2%) were identified as having malnutrition and 54.7% were identified as having low handgrip strength. Table 1 shows the difference between groups by malnutrition and handgrip strength status. Compared with the participants with good nutrition, those with malnutrition were older (86.2 ± 5.3 versus 84.6 ± 6.1 years, p = 0.011), had lower BMI (22.5 ± 4.1 versus 24.9 ± 2.8, p < 0.001), lower handgrip strength (21.3 ± 7.6 versus 27.7 ± 7.1 kg, p < 0.001), more cognitive impairment (65.2% versus 47.1%, p < 0.001), lower ADL levels (BI 72.8 ± 26.1 versus 92.7 ± 11.6, p < 0.001), lower gait speed (68.6% versus 54.1%, p = 0.015), higher rates of depressive symptoms (42.3% versus 8.5%, p < 0.001), higher CCI scores (1.7 ± 1.9 versus 1.0 ± 1.3, p < 0.001), higher rates of polypharmacy (70.7% versus 55.4%, p = 0.005), and a higher 4-year all-cause mortality rate (48.5% versus 24.1%, p < 0.001) (Table 1).

Compared with those classified with good handgrip strength, those with low handgrip strength were older (86.7 ± 4.9 versus 83.8 ± 6.2 years, p < 0.001) and had lower BMI (23.0 ± 3.6 versus 24.5 ± 3.8, P < 0.001), more cognitive impairment (71.4% versus 38.2%, p < 0.001), lower ADL scores (74.4 ± 25.2 versus 92.8 ± 13.1, p < 0.001), slower gait speed (75.7% versus 45.3%, p < 0.001), higher rates of depressive symptoms (33.9% versus 15.3%, p < 0.001), higher CCI scores (1.6 ± 1.9 versus 1.1 ± 1.4, p = 0.018), higher rates of polypharmacy (68.7% versus 56.3%, p = 0.020), more hearing impairment (90.1% versus 72.8%, p < 0.001), and higher rates of 4-year all-cause mortality (44.0% versus 27.2%, p = 0.002) (Table 1).

Fig. 1 shows the survival curve of those with and without malnutrition ( $\chi^2 = 22.03$ , P < 0.001) or low handgrip strength ( $\chi^2 = 10.74$ , P < 0.001) using Kaplan-Meier survival curves along with their respective log-rank tests.

### 3.2. Synergistic effects of low handgrip strength and malnutrition on 4-year all-cause mortality

Overall, participants with malnutrition and low handgrip strength were at significantly higher risk for 4-year all-cause mortality [Hazard

Abbreviations: MNA-SF, Mini Nutritional Assessment-Short Form, scores &lt; 12 indicate risk of malnutrition; MMSE, Mini-Mental State Examination, scores &lt; 24 indicate cognitive impairment; slow gait speed defined as &lt; 0.8 m/s; GDS-15, 15-item Geriatric Depression Scale, scores ≥ 5 indicate depressive symptoms; CCI, Charlson's Comorbidity Index.

ratio (HR): 2.42, 95% confident interval (CI): 1.65–3.53 for subjects with malnutrition; HR: 1.86, 95% CI: 1.28–2.72 for those with low handgrip strength] (Table 2). Based on the classifications of malnutrition and low handgrip strength, Groups 3 and 4 were at higher risk for 4-year all-cause mortality (HR: 1.83, 95% CI: 0.99–3.38 for Group 3; HR: 3.14, 95% CI: 1.93–5.12 for Group 4). After adjusting for covariates, Group 3 and Group 4 remained significantly associated with 4 year all-cause mortality (adjusted HR: 2.05, 95% CI: 1.04–4.01 for Group 3; adjusted HR: 3.41, 95% CI: 1.93–6.04 for Group 4). The 4-year survival curves of the four groups based on nutritional status and handgrip strength are shown in Fig. 2 ( $\chi^2 = 28.64$ , p < 0.001).

## 4. Discussion

### 4.1. Overall results

This prospective longitudinal cohort study evaluated the synergistic effects of malnutrition and low handgrip strength on the prediction of 4-year all-cause mortality among male older adults living at the VCH. Results of the present study showed that 50.2% of the participants were classified as having malnutrition, a rate similar to those in previous studies (Cereda et al., 2016; Kaiser et al., 2010). The present study showed that participants with malnutrition were at significantly higher

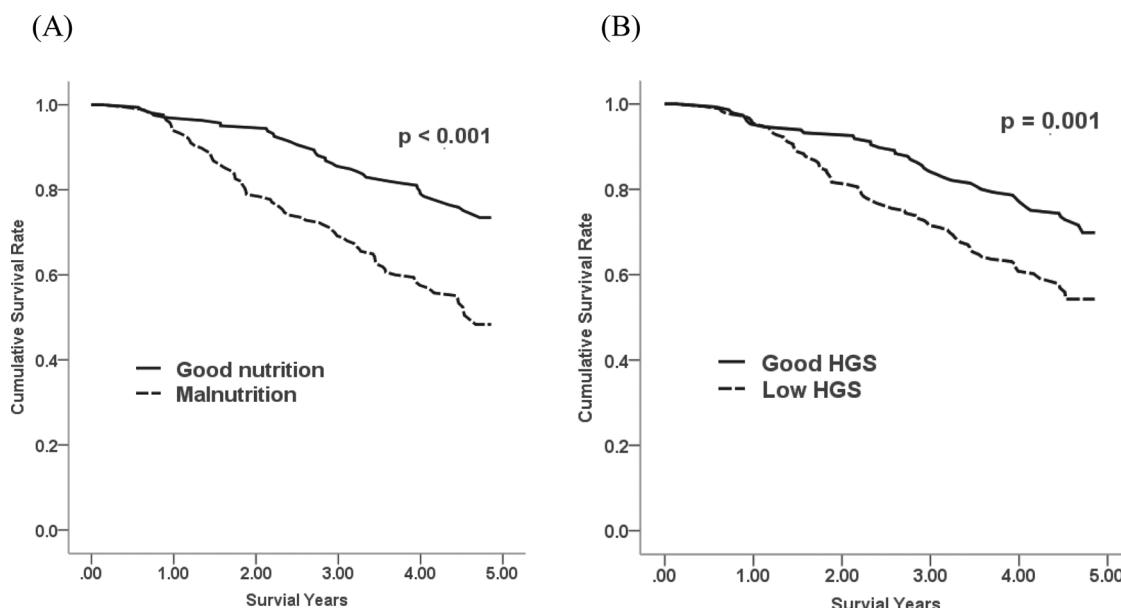

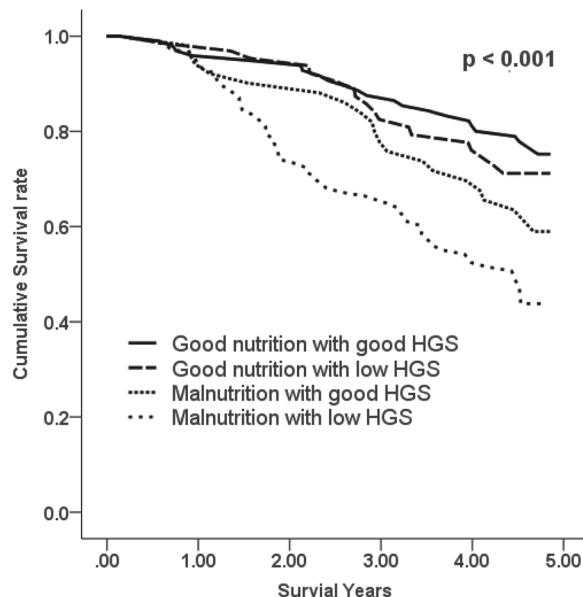

Fig. 1. Kaplan-Meier survival curves of older adults (A) with or without malnutrition and (B) low handgrip strength (HGS).

risk for 4-year all-cause mortality than those without. Furthermore, the synergistic effect of low handgrip strength with malnutrition increased the adjusted hazard ratio of 4-year all-cause mortality from 2.05 to 3.41. This study is the first to report this significant synergistic effect of low handgrip strength and malnutrition with this design.

#### 4.2. Adverse outcomes associated with malnutrition

Older age increases the risk of malnutrition, multimorbidity, and disability. Aging also places people at risk of accumulating chronic diseases and impairments—such as cognitive and physical decline, depressive symptoms, socioeconomic decline, and poor oral health—all of which can contribute to the development of malnutrition and its adverse outcomes (Favaro-Moreira et al., 2016). Malnutrition has been reported to be significantly associated with older age, polypharmacy, physical and cognitive decline, constipation, dementia, eating dependence, poor appetite, institutionalization, and frailty (Favaro-Moreira et al., 2016). In our present study, malnutrition was related to older age, lower BMI, lower handgrip strength, higher physical and cognitive impairment, lower gait speed, more depressive symptoms, more comorbidity, and polypharmacy, and which could also predict mortality. Understanding the risk factors for malnutrition in male older adults can

help with the development of integrated intervention programs to improve outcomes in those at risk of malnutrition (Kang et al., 2019; Ngandu et al., 2015).

#### 4.3. The relationship of low handgrip strength and malnutrition

Much evidence shows that lower physical function, as indicated by lower handgrip strength or slower gait speed, frailty, and sarcopenia, is more prevalent in older adults with malnutrition (Wei et al., 2017). In addition, there is increasing awareness of the overlap between physical dysfunction and malnutrition, as well as the common interventions for both (Laur, McNicholl, Valaitis, & Keller, 2017). Currently, no universally accepted definition of malnutrition exists, despite the many consensus statements and assessment tools available. These assessment tools were developed based on the definition of malnutrition by White et al. as an overall “decline in lean body mass, with the potential for functional impairment” (White, Guenter, Jensen, Malone, & Schofield, 2012). The Academy of Nutrition and Dietetics and ASPEN recommendations include diminished functional status as one of their six criteria to identify malnutrition. This recommendation acknowledges that individual clinical markers of body composition and physical dysfunction characterize malnutrition; however, it failed to address the interaction between malnutrition and physical dysfunction in terms of clinical outcome. Recent research found malnutrition associated with the need for more complex care among the oldest old male residents of long-term care facilities with mobility-type prefrailty or frailty, a correlation not found among those with good physical function. This result reinforces the relationship between nutritional status and physical function (Chou et al., 2019).

#### 4.4. Interaction and synergistic effect of malnutrition and handgrip strength

In the present study, we found that malnutrition was significantly associated with low handgrip strength and slow gait speed, compatible with a previous study (Akbar & Setiati, 2018). Malnutrition is a widely known key mechanism in the pathogenesis of sarcopenia. Sarcopenia, in addition to the negative result of malnutrition, is also a negative consequence of physical inactivity, chronic diseases, or hormonal, cytokine, or metabolic imbalances (Campins et al., 2017; Jeejeebhoy, 2012), and is well known to lead to such adverse health outcomes as falls, institutionalization, functional dependence, and even mortality (Chen et al., 2014). A recent population-based cross-sectional study reported that excessive carbohydrate and inadequate protein intake could lead to malnutrition and was associated with low handgrip strength in community-dwelling older adults (Kim et al., 2019). Another study reported that low handgrip strength could independently predict nutritional status (Flood, Chung, Parker, Kearns, & O'Sullivan,

2014). In the present study, participants with malnutrition or low handgrip strength were at higher risk for 4-year all-cause mortality. Fully one-third of those with malnutrition also had low handgrip strength, which increased the hazard ratio of mortality from 2.05 to 3.41. The potential interactive mechanism between malnutrition and muscle strength may be a closed-loop cyclical association. Certain bio-psycho-social factors may also affect appetite and food consumption, such as loss of taste sensation, chewing difficulties, and impairment in digestion function (Murphy, 2008; Nieuwenhuizen, Weenen, Rigby, & Hetherington, 2010). The negative consequence of these conditions are usually compounded by physical function impairments in the ability to prepare food and psychological or cognitive impairment such as depression and dementia (Favaro-Moreira et al., 2016), which may increase the risk of co-existing malnutrition and physical decline.

#### 4.5. Limitations

Despite our best efforts, this study still has some limitations. First, the participants were all retired male veterans living in one facility, VCH. Their characteristics were homogenous and all were male. The results of the present study might not apply to the general population. Second, nutritional status was assessed by using MNA-SF, which might not be sensitive enough. However, Kaiser et al. did find that MNA-SF could detect the precise nutritional condition of older adults (Kaiser et al., 2009). Third, the present study did not measure nutritional status or handgrip strength repeatedly, so that any dynamic changes in nutritional status or handgrip strength could not be estimated. Longitudinal studies may yield more robust findings.

#### 4.6. Conclusions

Malnutrition was an independent risk factor for 4-year all-cause mortality and low handgrip strength had the synergistic effect of increasing the risk of mortality. A further intervention study is needed to determine the effectiveness of integrated programs for those at risk for both malnutrition and low handgrip strength, to lower the risk of adverse health outcomes in these older adults.
